

Chapter 1 Warm-Up: Python `print()` Statements

Prof. Jordan C. Hanson

August 24, 2026

1 Printing Text in Python

1. The Python `print()` function displays text on the screen. A string of text is placed inside quotation marks and then inside the parentheses of the `print()` function.

- Create a new Python file called `table_of_contents.py`. Begin by printing the title of the book:

```
print("Python Programming: A First Course")
```

- Add a second `print()` statement containing an empty string. What effect does this have on the output?

```
print("")
```

- Now print the first entry in the table of contents. Use periods to connect the chapter title on the left to the page number on the right:

```
print("Chapter 1: Getting Started.....1")
```

- Run the program. At this point, your output should contain a book title, a blank line, and the first chapter of the table of contents.

- How many `print()` statements are required to produce the complete table of contents, including the blank line after the book title? Sketch a plan of your code below before beginning in Google CoLab.

- Run your program and compare its output with the example above. Adjust your code until the output matches the requirement.

2 Warm-Up Exercise

1. Complete the program using only simple Python statements and the `print()` function. Your program should produce the following table of contents:

```
Python Programming: A First Course
```

```
Chapter 1: Getting Started.....1
Chapter 2: Variables and Data Types.....17
Chapter 3: Making Decisions.....35
Chapter 4: Repeating with Loops.....57
Chapter 5: Writing Functions.....81
```

- Use one `print()` statement for each line.
- Keep each chapter title on the left and its page number on the right. Add enough periods between them so that the page numbers align.

3 Name and Student ID

1. Please write your name and student ID below, and submit this document to the instructor as you leave class.
